Last updated: 2026-09-10

How do I investigate a failed workflow execution?

- 1 Open the workflow, then click Execution History.
- 2 Find the failed run by timestamp.
- 3 Click into the run to see the failed step highlighted in red.
- 4 Read the error message attached to the failed step.
- 5 Check whether the integration credential is valid.
- 6 Retry only after addressing the underlying cause.

What does HTTP 400 mean?

A 400 (Bad Request) usually means the request sent to an integration or API was malformed — missing a required field, wrong data type, or invalid JSON. Check the request body against the integration's documentation.

What does HTTP 401 mean?

A 401 (Unauthorized) means authentication failed. This is almost always a credential issue: an expired API key, revoked OAuth token, or wrong authorization header. Check the connected credential in Settings → Integrations. Never paste secret credentials into a support chat.

What does HTTP 403 mean?

A 403 (Forbidden) means the request was authenticated but not allowed. Common causes: insufficient permission scopes, a role that lacks access, or a workspace setting blocking the action. Check the integration's scopes and your workspace role.

What does HTTP 404 mean?

A 404 (Not Found) means the requested resource or endpoint does not exist. Confirm the URL, resource ID, workspace slug, and environment (production vs. sandbox). A common cause is referencing a record that was deleted or belongs to a different workspace.

What does HTTP 409 mean?

A 409 (Conflict) means the request conflicted with the current state of the resource. Common causes: creating a record with a duplicate unique key, updating a record that was just modified, or concurrent writes to the same resource. Retrying after a short delay often resolves transient conflicts.

What does HTTP 422 mean?

A 422 (Unprocessable Entity) means the request was well-formed but failed validation. Common causes: a field that doesn't match the expected format, a value outside the allowed range, or a required field missing a valid value. The error response usually identifies the specific field.

What does HTTP 429 mean?

A 429 (Too Many Requests) means a rate limit was reached. FlowStack applies rate limits per workspace and per integration. Check your recent execution volume and retry after the documented retry window. 429s typically clear within 60 seconds if you stop sending requests.

What does HTTP 500 mean?

A 500 (Internal Server Error) means the upstream service returned an unexpected error. This is usually the connected integration's problem, not FlowStack's. Retry once after 60 seconds. If the error persists, check the integration provider's status page.

What does HTTP 502/503 mean?

A 502 (Bad Gateway) or 503 (Service Unavailable) means the upstream service is temporarily unavailable. Wait 60 seconds and retry. If the error recurs across multiple workflows, the integration provider likely has an outage — check their status page.

What does a timeout mean?

A timeout means the request didn't complete within the expected time window (typically 30 seconds). Before retrying, check the execution history to see if the original request actually completed — otherwise a retry can create a duplicate. If the workflow continued in the background, do not retry.

Why did my integration connection fail?

Common causes: the OAuth token expired, the API key was rotated, the integration provider revoked access, or the workspace credential was deleted. Go to Settings → Integrations → [Integration Name] → Reconnect. If reconnecting doesn't resolve it, collect the integration name, visible error, approximate time, and workflow name for support review.

How do I reconnect an integration?

Go to Settings → Integrations, find the integration showing an error, and click Reconnect. You'll be asked to sign in to the provider again. Existing workflows using that integration resume automatically.

once the credential is refreshed.

Can I see what data was sent to an integration?

Yes, for integrations that support logging. Go to the failed execution in Execution History, click the failed step, and open the Request tab. Sensitive fields (tokens, passwords) are redacted automatically. If you need request/response logs for an integration that doesn't expose them, contact support.

How do I test a workflow without triggering the real integration?

Use the Test Mode toggle in the workflow editor. Test Mode logs what would have been sent without making the real API call. This is useful for validating configuration changes without side effects.

How do I roll back a workflow to a previous version?

Open the workflow, click the Version dropdown in the top-right, and select a previous version. Click Restore. The restored version becomes the active version immediately. Version history is retained for 90 days on Growth, 1 year on Scale, and unlimited on Enterprise.

How do I find the execution ID for support?

Open the failed execution in Execution History. The execution ID is shown in the URL and in the Details panel on the right. Copy it and include it in your support message — it helps support find the exact run without ambiguity.

Screenshots

A screenshot can help diagnose UI errors. Before uploading, redact passwords, full card numbers, CVVs, one-time authentication codes, API secrets, and any other sensitive values.
